

INTRODUCING MACHINE LEARNING

Jan-Philipp Kolb

22 Mai, 2019

MACHINE LEARNING - COMPONENTS

- ▶ Feature Extraction + Domain knowledge (Import and Data Wrangling)
- ▶ Feature Selection
- ▶ Choice of Algorithm (Regression or classification, regularization, decision trees, k-Means clustering, ...)
- ▶ Training
- ▶ Choice of Metrics/Evaluation Criteria
- ▶ Testing

FEATURE SELECTION IN MACHINE LEARNING,

- ▶ feature selection is the process of selecting a subset of relevant features (variables, predictors) for use in model construction.

FOUR REASONS FOR FEATURE SELECTION:

- 1.) simplification of models to make them easier to interpret by researchers/users,
- 2.) shorter training times,
- 3.) to avoid the curse of dimensionality,
- 4.) enhanced generalization by reducing overfitting (formally, reduction of variance)

THE CURSE OF DIMENSIONALITY

In machine learning, “dimensionality” simply refers to the number of features (i.e. input variables) in your dataset.

When the number of features is very large relative to the number of observations in your dataset, certain algorithms struggle to train effective models. This is called the “Curse of Dimensionality,” and it’s especially relevant for clustering algorithms that rely on distance calculations.

Dimensionality Reduction

SUPERVISED VS UNSUPERVISED LEARNING

SUPERVISED LEARNING

- ▶ we have prior knowledge of what the output values for our samples should be.

TASK: FIND R-PACKAGES

Go to <https://cran.r-project.org/> and search for packages that can be used for:

- ▶ lasso regression
- ▶ random forests
- ▶ gradient boosting
- ▶ neural networks
- ▶ clustering

TASK VIEW MACHINE LEARNING

CRAN Task View: Machine Learning & Statistical Learning

Maintainer: Torsten Hothorn

Several add-on packages implement ideas and methods developed at the borderline between computer science and statistics - this field of research is usually referred to as machine learning. The packages can be roughly structured into the following topics:

- *Neural Networks and Deep Learning* : Single-hidden-layer neural network are implemented in package [nnet](#) (shipped with base R). Package [RSNNs](#) offers an interface to the Stuttgart Neural Network Simulator (SNNS). [rnn](#) implements recurrent neural networks. Packages implementing deep learning flavours of neural networks include [deepnet](#) (feed-forward neural network, restricted Boltzmann machine, deep belief network, stacked autoencoders), [RcppDL](#) (denoising autoencoder, stacked denoising autoencoder, restricted Boltzmann machine, deep belief network) and [h2o](#) (feed-forward neural network, deep autoencoders). An interface to [tensorflow](#) is available in [tensorflow](#).

INSTALL ALL PACKAGES OF A TASK VIEW

```
install.packages("ctv")  
ctv::install.views("MachineLearning")
```

PREDICTION VS. CAUSATION IN REGRESSION ANALYSIS

Paul Allison

There are two main uses of multiple regression: prediction and causal analysis. In a prediction study, the goal is to develop a formula for making predictions about the dependent variable, based on the observed values of the independent variables. . . . In a causal analysis, the independent variables are regarded as causes of the dependent variable. The aim of the study is to determine whether a particular independent variable really affects the dependent variable, and to estimate the magnitude of that effect, if any

WHAT IS SUPERVISED LEARNING?

Supervised learning includes tasks for “labeled” data (i.e. you have a target variable).

- ▶ In practice, it's often used as an advanced form of predictive modeling.
- ▶ Each observation must be labeled with a “correct answer.”
- ▶ Only then can you build a predictive model because you must tell the algorithm what's “correct” while training it (hence, “supervising” it).
- ▶ Regression is the task for modeling continuous target variables.
- ▶ Classification is the task for modeling categorical (a.k.a. “class”) target variables.

RANDOM FOREST

Random forest aims to reduce the previously mentioned correlation issue by choosing only a subsample of the feature space at each split. Essentially, it aims to make the trees de-correlated and prune the trees by setting a stopping criteria for node splits, which I will cover in more detail later.

WHAT ARE THE ADVANTAGES AND DISADVANTAGES OF DECISION TREES?

Advantages: Decision trees are easy to interpret, nonparametric (which means they are robust to outliers), and there are relatively few parameters to tune.

Disadvantages: Decision trees are prone to be overfit.

- ▶ This can be addressed by ensemble methods like random forests or boosted trees.

ENSEMBLING

Ensembles are machine learning methods for combining predictions from multiple separate models.

BAGGING

attempts to reduce the chance overfitting complex models.

- ▶ It trains a large number of “strong” learners in parallel.
- ▶ A strong learner is a model that’s relatively unconstrained.
- ▶ Bagging then combines all the strong learners together in order to “smooth out” their predictions.

BOOSTING

attempts to improve the predictive flexibility of simple models.

- ▶ It trains a large number of “weak” learners in sequence.
- ▶ A weak learner is a constrained model (i.e. you could limit the max depth of each decision tree).
- ▶ Each one in the sequence focuses on learning from the mistakes of

RANDOM FOREST

- ▶ Ensemble learning method - multitude of decision trees
- ▶ Random forests correct for decision trees' habit of overfitting to their training set.

Random Forest Simplified

GRADIENT BOOSTING

Gradient boosting is a machine learning technique for regression and classification problems, which produces a prediction model in the form of an ensemble of weak prediction models, typically decision trees. It builds the model in a stage-wise fashion like other boosting methods do, and it generalizes them by allowing optimization of an arbitrary differentiable loss function.

The idea of gradient boosting originated in the observation by Leo Breiman that boosting can be interpreted as an optimization algorithm on a suitable cost function.

Breiman, L. (1997). "Arcing The Edge". Technical Report 486. Statistics Department, University of California, Berkeley.

Advantages of gradient boosting

- ▶ Often provides predictive accuracy that cannot be beat.
- ▶ Lots of flexibility - can optimize on different loss functions and provides several hyperparameter tuning options that make the function fit very flexible.
- ▶ No data pre-processing required - often works great with categorical and numerical values as is.
- ▶ Handles missing data - imputation not required.

Disadvantages OF GRADIENT BOOSTING

- ▶ GBMs will continue improving to minimize all errors. This can overemphasize outliers and cause overfitting. Must use cross-validation to neutralize.
- ▶ Computationally expensive - GBMs often require many trees (>1000) which can be time and memory exhaustive.
- ▶ The high flexibility results in many parameters that interact and influence heavily the behavior of the approach (number of iterations, tree depth, regularization parameters, etc.). This requires a large grid search during tuning.
- ▶ Less interpretable although this is easily addressed with various tools (variable importance, partial dependence plots, LIME, etc.).

TWO TYPES OF ERRORS FOR TREE METHODS

BIAS RELATED ERRORS

- ▶ Adaptive boosting
- ▶ Gradient boosting

VARIANCE RELATED ERRORS

- ▶ Bagging
- ▶ Random forest

MODERN MACHINE LEARNING ALGORITHMS

Categorizing machine learning algorithms is tricky, and there are several reasonable approaches; they can be grouped into generative/discriminative, parametric/non-parametric, supervised/unsupervised, and so on.
